

Revision 3 is a targeted closure pass that addresses the remaining implementation-gate issues identified in the Rev 2 review.

| Remaining Issue                                   | Revision 3 Response                                                                                                                                  |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Emitter gate not closed                           | Architecture now names the Phase 1 emitter explicitly:<br><code>openclaw message send --channel telegram --target &lt;id&gt; --message "...".</code> |
| Scheduler choice still ambiguous                  | Revision 3 explicitly selects <b>OpenClaw native cron</b> as the Phase 1 scheduler.                                                                  |
| Registration mechanism not fully specified        | Revision 3 defines agent-follow-up as a local Node.js CLI in the project directory with an invocation path and command contract.                     |
| Conditional observability undefined               | Revision 3 removes vague conditional language from Phase 1 and narrows support to process-backed and marker-backed tasks only.                       |
| Unknown threshold N not defined                   | Revision 3 sets the default unknown-state threshold to <b>2 watchdog cycles</b> .                                                                    |
| resolution_status vs last_observed_status unclear | Revision 3 adds an explicit semantic distinction between observed transient state and resolved terminal outcome.                                     |
| Raw PID as observable_id is unsafe                | Revision 3 changes the process-backed observable identity to an owned marker/sentinel path, with PID as optional secondary evidence only.            |
